# Stand Survey \& Growth Modeling for the Fort St. John TSA 

Prepared for<br>Don Rosen<br>Greg Taylor, RPF<br>Canadian Forest Products Limited<br>Chetwynd, BC

Project: CFC-004

January 17, 2003

## Executive Summary

Riverside Forest Products Ltd., as part of their Forest Practices Code (FPC) pilot project on TFL 49, developed a prototype silviculture survey and modeling system to assess reforestation obligations at the landscape level. This report describes the first steps in adapting the prototype system for use in the Fort St. John TSA. The initial Riverside system uses stand, site and tree information collected in surveys 10 years post-harvest to predict merchantable volumes 80 years post-harvest for lodgepole pine and interior spruce stands. Silviculture obligations are met if the overall average predicted merchantable volume meets or surpasses the target merchantable volume set for the harvested area.

For the Fort St. John TSA, the model to predict future merchantable volumes was re-fit to use survey data 15 years post-harvest as the inputs and provide merchantable volumes for lodgepole pine and interior spruce stands 80,90 and 100 years post-harvest as the outputs. In addition, the post-stratification procedures for the survey data have been simplified and improved using inventory attributes and target stocking standards as the variables to assign plots to the required strata for determination of future merchantable volumes.

The proposed survey methodology uses a combination of full-measure and count-plots established on a 100 m grid. The full-measure plots are established on the 200 m grid where all trees are measured for height, species, and health condition. The count-plots are established on a 100 m grid between the fullmeasure plots where less detailed measurements are taken. Pins are used to mark the location of the full-measure plots so they can be relocated and included in subsequent surveys. This will then provide data that can be used to estimate change in these young stands over time. In addition, the use of a grid allows linkage to a growth and yield monitoring program where permanent sample plots can be established on a small subset of the points used for the full measure plots.

To fully implement the silviculture survey and modeling system in the Fort St. John TSA additional work is required to improve estimates of site productivity and include projections of aspen and mixedwood merchantable volumes and changes in species composition in the model. The later are dependent on improved growth and yield modeling of aspen and mixedwood stands which has been identified as a high priority for the TSA.

## 1. INTRODUCTION

### 1.1 BACkGROUND

Participants in the Fort St. John Results Based Forest Practices Code pilot project expressed interest in adapting the prototype silviculture survey and modeling system developed by Riverside Forest Products for TFL 49. ${ }^{1,2}$ The prototype system, developed for lodgepole pine (PI) and interior spruce (Sx) stands, was completed in 2001-02 by Riverside as part of their Results Based Code pilot project. The primary objectives of the system were to assess reforestation performance at a level of resolution above the individual cutblock, allow silviculturalists more options to achieve the desired stand at harvest for the lowest costs, and to highlight the relationships between silviculture activities and future yields. A key component of the prototype system is the ability to compare silviculture performance against a predetermined target. The major steps in the system are to:

1) Use a simple survey to collect information on regenerated stands.
2) Use the survey information to predict future harvest volume.
3) Compare the predicted volume to a target future volume for those blocks.

This results based system ensures that overall silviculture performance goals are achieved while avoiding the high cost of micro-managing individual blocks and portions of blocks.

### 1.2 Project Goal \& Objectives

The primary goal of this project is to adapt the Riverside silviculture survey and modeling system to the Fort St. John TSA for the results based code pilot project. The system will be adapted for PI and Sx this year and aspen (At) and At/conifer mixtures in subsequent years.

The specific objectives of this project are to:

1) Re-fit the Pl and Sx models developed for Riverside with different post-harvest times for the survey and subsequent harvest. ${ }^{3}$
2) Identify potential linkages between the survey and modeling system and monitoring requirements.
3) Provide sufficient information to describe the survey and modeling system in the Fort St. John sustainable forest management plan (SFMP).
4) Assess the direct applicability of the Riverside system to the Fort St. John TSA and document required adjustments, including those needed for At and At/conifer stands. (The intent is that adjustments not addressed in this project will be included in a future research proposal ${ }^{4}$ ).
[^0]
### 1.3 Terms of Reference

This project was completed by J.S. Thrower \& Associates Ltd. (JST) for Canadian Forest Products Ltd. (Canfor), Fort St. John operations. The JST project team was Eleanor McWilliams, MSc RPF, Jim Thrower, PhD RPF, lan Cameron, MSc RPF, and Guillaume Thérien, PhD. The Canfor project leaders were Don Rosen and Greg Taylor, RPF.

Three main groups collaborated in developing this system: the Ministry of Forests lead policy development and provided the TASS simulations; the licensees (Riverside and Canfor) lead operational implementation; and J.S. Thrower \& Associates lead the design of the survey and modeling system. Key contributors from the Ministry of Forests were Pat Martin, RPF, Lorne Bedford, RPF, Ken Polsson, and Wendy Bergerud. Shane Browne-Clayton, RPF, is the Riverside project leader, and Gary Bouthillier (Resource West Consulting Ltd., Kelowna) provided valuable input into the survey design.

## 2. STAND SURVEY

### 2.1 Overview

The key components of the proposed stand survey (described below) are:

1) Stands are surveyed 15 years after harvest to estimate the predicted merchantable volume (PMV) at a given age (80, 90, or 100 years after harvest).
2) Sample plots are located on a 100 m grid (generated from UTM coordinates), and all grid points in the net area to be reforested (NAR) are sampled.
3) Full-measure plots are located on the 200 m grid points, and count plots are located on the 100 m grid points.
4) Both plot types use a 3.99 m radius plot $\left(50 \mathrm{~m}^{2}\right)$ to measure tree attributes. A 5.64 m radius site index plot $\left(100 \mathrm{~m}^{2}\right)$ is established at the full-measure plots to collect site tree data.
5) Measurements in full-measure plots include:
a) Species, height (visually estimated), and health of all trees.
b) An assessment of stocked or not stocked for each quadrant (a stocked quadrant must contain at least one healthy free-growing tree).
c) An assessment of non-productive area and brush.
d) Height and age of one site tree per species.

Full-measure plots are marked with a steel ${ }^{5}$ pin and GPS coordinates are taken for future relocation to include in subsequent surveys.
6) Measurements in count plots are also recorded by quadrant and include only:
a) An assessment of stocked or not stocked for each quadrant, and why quadrants are not stocked (e.g., brush, non-productive (NP) area, health).
b) A tally of trees by species.

### 2.2 Survey Objectives

The goal of the survey is to describe stand characteristics in sufficient detail to estimate the PMV at 80, 90 , or 100 years after harvest to compare with a target merchantable volume (TMV) for that age. The objectives of the stand survey are to:

1) Measure tree conditions, stand structure, and site productivity (where possible) to predict future volume.
2) Produce inventory labels.
3) Identify potential areas for silviculture treatments.
4) Update block maps to define areas where volume should be predicted and where other values take precedence (e.g., wildlife).
[^1]
### 2.3 Target Population

The target population to sample in a given year is the NAR created from harvesting 15 years previously. For example, the target population to sample in the year 2003 is the NAR from harvesting in 1988. The modeling procedures developed in this project assume stands are surveyed 15 years after harvest.

### 2.4 Post-Stratification

Three primary objectives to post-stratify the target population are to:

1) Assess regeneration performance. Stands are grouped to calculate TMV and PMV.
2) Delineate forest-cover polygons.
3) Identify areas for silviculture treatments.

A secondary objective to post-stratify the target population is to:

1) Improve integration of silviculture and inventory records and the link between silviculture decisionmaking and timber supply.

The target population is post-stratified using information from the inventory labels and target stocking standards (TSS). For each defined stratum, a TMV is set, and data from all plots are pooled to determine an overall mean number of stocked quadrants (MSQ), effective age, and site index to calculate the PMV. The procedures for post-stratification are described in Sections 2.5.2 and 2.6.1, and the procedures to compile the data are described in Section 4.

### 2.5 Office Procedures

### 2.5.1 Map \& Previous Data

A Silviculture Prescription (SP) map (or equivalent) should be used to develop the plot locations of the stand survey and should be updated following each survey. This map should show block boundaries, NP area, non-commercial cover (NCC), wildlife tree patches (WTPs), riparian management areas (RMAs), permanent access structures (PASs), and temporary roads. If permanent sample points were established in a previous survey (Section 5.1), the data should be downloaded to hand-held computers for comparison and error checked during the survey. The surveyor should be familiar with the block history.

### 2.5.2 Office Stratification

Prior to field sampling, the following information should be added to the survey map:

1) Transfer NAR boundary to the survey map (the NAR is the target area to sample).
2) Transfer TSS boundaries from the SP to the survey map.
Standards units (SUs) can be combined if they have: a) the same TSS; and b) the same preferred and acceptable $(p+a)$ species. Record the TSS and the $p+a$ species for each unit (this information is required during the survey).

Figure 1. Example of sample points on a $100(\cdot)$ and $200(\diamond) \mathrm{m}$ grid.

### 2.5.3 Plot Locations

Sample plots are located on a 100 m grid (Figure 1) using UTM NAD 83 coordinates. These grid points can be generated in the GIS by plotting points evenly divisible by 100. Plot locations should be marked on the map prior to field sampling and all points in the NAR should be sampled.

### 2.6 Field Sampling

### 2.6.1 Stratification

During field sampling the following information should be added to the survey map:

1) Update NAR boundaries if necessary.
2) Map inventory polygons. Follow current procedures to map inventory polygons using species composition, site productivity, and stand density. Distinguish between areas considered SR and NSR.
3) Map potential treatment units. If the cutblock contains a viable treatment unit, add to the map the approximate location of the treatment unit and describe the treatment opportunity.

### 2.6.2 Full-Measure Plots

Each full-measure plot includes a $50 \mathrm{~m}^{2}$ ( 3.99 m radius) plot divided into quadrants along cardinal directions to measure tree attributes and a $100 \mathrm{~m}^{2}$ ( 5.64 m radius) plot to collect height and age data from site trees (located at the same plot center) (Figure 2). Suitable site trees have three or more years height growth above breast height. Site tree data should be collected from one tree of each species located in the site index plot with a suitable site tree.

## Plot Location

Full-measure plots are established on the 200 m grid. Plot centers should be permanently marked with a steel pin and GPS coordinates recorded. Plot locations should be documented in the GIS. These sample points should not be visible when walking through the stand to avoid treating the plot area differently than other portions of the stand (which may bias the information from the sample point at subsequent measurements).
Main Plot - 50 m $^{2}$
Quadrant Information - Record each quadrant as

Figure 2. Full-measure and count plot design. stocked if it contains at least one healthy tree of an acceptable species that is free of brush competition (according to current free growing regulations). If a non-stocked quadrant could support tree growth, comment on why there are no trees (e.g., type of NP ground, missed plantable spots, brush competition, health problems).

Tree Information - Data for each tree in the plot includes:
i) Quadrant number (1-4).
ii) Tree species.
iii) Height (measure some for reference and visually estimate others).
iv) Forest health codes (use the same codes used in other silviculture surveys).

Brush Information - In each quadrant record percent cover and average height of brush by species.

NP Area Information - In each quadrant record the type and percent cover of NP area (e.g., rock, water).

## Site Index Plots - 100 m $^{2}$

Record site index information for one site tree of each species from the site index plot located at each plot center. Site trees are:
i) The tallest tree in the $100 \mathrm{~m}^{2}$ plot for that species.
ii) Undamaged (stem damage resulting in less than $5 \%$ reduction in height growth).
iii) Not overtopped by other trees or competing vegetation where height growth may be affected.

The second tallest tree can be measured for site index if the tallest is not suitable. This must be noted on the field card. Information collected for each tree should include:
i) Total height.
ii) Age at breast height (yrs).
iii) Total age (yrs).
iv) Rank in height relative to other trees in the plot of that species (e.g., tallest, 2nd tallest, etc.).

### 2.6.3 Count Plots

Count plots consist of a $50 \mathrm{~m}^{2}$ plot to collect stocked quadrant information.

## Plot Location

Count plots are established at the 100 m grid points between each full-measure plot. Count plots are not permanently marked, and GPS coordinates are not recorded.
Main Plot - 50 m $^{2}$
Quadrant Information - Record each quadrant as stocked if it contains at least one healthy tree of an acceptable species that is free of brush competition (the same as in full-measure plots). For non-stocked quadrants, record whether the quadrant is NP (and type of NP) or could support tree growth. If a nonstocked quadrant can support tree growth, comment on why there are no trees (e.g., missed plantable spots, brush competition, health problems, etc.).

Tree Information - Tally the number of trees by species. This is used to estimate stand density and species composition.

## 3. PREDICTING FUTURE VOLUME

### 3.1 Overview

The same TASS simulations used to develop equations for Riverside were used in this project. TASS was used to simulate 433 different Pl and Sx stand types with varying species composition, stand density, spatial distributions, and ingress patterns. The simulated stands were surveyed using the stem maps generated for a range of young stand ages using the procedures described in Section 2. Survey statistics were compiled and compared to merchantable volumes 80,90 , and 100 years after harvest. The single best predictor of future volume was mean number of stocked quadrants (MSQ). A quadrant is considered stocked when it has at least one healthy tree of an acceptable species that is free of brush competition.

Based on these results, a model was developed to predict merchantable volumes 80, 90, and 100 years after harvest from survey data collected 15 years after harvest. Model inputs include species composition (limited to $\mathrm{PI}, \mathrm{Sx}$, or PISx), MSQ, site index, and effective total stand age (determined from site index and total average site tree height).

### 3.2 Objectives

The goal of predicting future stand merchantable volumes is to compare the estimates with target merchantable volumes to measure silviculture performance. The objectives of the modeling are to:

1) Predict stand merchantable volumes 80,90 , and 100 years after harvest.
2) Use the simplest method that accounts for key factors influencing future volume.

### 3.3 Model Development

### 3.3.1 TASS Simulations

The TASS simulations generated a wide range of stand structures to develop and test a model to predict future merchantable volumes from stand survey data. These simulations were completed by the MOF Research Branch and included 433 combinations of planting and natural stand densities, species compositions, and spatial and temporal distributions (Table 1). The various factors were combined in a factorial structure so that initial stand density ${ }^{6}$ ranged from 400 to $9,400 /$ ha and species composition ranged from $100 \% \mathrm{PI}$ or Sx and a full range of mixtures.

Table 1. Factors in the matrix of TASS runs used for model development.

| Factor | Level |
| :---: | :---: |
| Site Index | 20 m |
| Species | PI, Sx |
| Planting Density (no/ha) | 0, 400, 800, 1,000, 1,200, 1,400 ${ }^{\text {a }}$ |
| Natural Density (no/ha) | 0, 400, 800, 1,200, 1,600, 2,000, 5,000, 8,000 |
| Spatial distribution of naturals | Random, Clumped ${ }^{\text {b }}$ |
| Ingress period of naturals | TASS default (truncated Normal (2, 1.5)), Poisson (4.0) ${ }^{\text {c }}$ |
| ${ }^{\text {a }}$ Planting was assumed to occur one year after harvest with one year old stock. |  |
| ${ }^{\text {b }}$ Naturals were apportioned $75 \%$ to clumps and $25 \%$ random, with an average of 25 trees/clump. |  |
| ${ }^{c}$ Normal $(2.0,1.5)$ is a Normal distribution with mean of 2.0 and standard deviation of 1.5. Poisson (4.0) is a Poisson distribution with a mean and variance of 4.0. |  |

6 The number of trees simulated by TASS prior to mortality.

The height vigor coefficient was included in all simulations (so top height trees track the height-age curve for the assigned site index, regardless of stand density). Each TASS simulation was for a 3.0 ha block $(100 \times 300 \mathrm{~m})$. No operational adjustment factors (OAFs) were applied, however, the natural clumped distributions with no planting resulted in holes distributed throughout the stands.

The following were generated for each TASS simulation:

1) A standard run summary with output from ages $1-15$ and then every five years to age 120 .
2) Stem maps for ages $10,13,15$, and 18 years. These included $x$ - $y$ coordinates, species, and heights. Stand density at these ages varied due to ingress and mortality patterns simulated in TASS.

### 3.3.2 Simulated Surveys

We simulated surveys in each stand using the survey procedures (Section 2) where plots were established on randomly oriented 25 m grids. This gave about 48 plots for each simulated survey (a 25 m grid gives 16 plots/ha, each stand is 3 ha ). For each plot, the species and height of each tree in each quadrant was recorded. For each of the 433 TASS simulations, 30 surveys were simulated for each of ages $10,13,15$, and 18 years, for 51,960 simulated surveys (Table 2).

### 3.3.3 Model Fitting ${ }^{7}$

The Riverside project showed that MSQ was the best predictor of future volume (Table 2). Several equation forms were tested with the best fit provided by a quadratic equation:

$$
\mathrm{PMV}=a+b^{*} \mathrm{MSQ}+c^{\star} \mathrm{MSQ}^{2}
$$

Where PMV is predicted merchantable volume at a defined post-harvest time; $\boldsymbol{a}, \boldsymbol{b}$, and $\boldsymbol{c}$ are coefficients (Appendix I); and MSQ is the number of mean stocked quadrants from the sample of a stand or stratum. Analyses showed that anamorphic curves (parameters $b$ and $c$ are held constant) could be fit to the data with separate intercepts (parameter a) for each of 12 stand age and species combinations. In the Riverside project, four stand ages ( $5,7,10$, and 13 ) were used to represent the range of potential stand ages 10 years postharvest. The three species groups were pure $\mathrm{PI}(\geq 80 \% \mathrm{PI}$ based on stand density at the time of the survey), pure Sx ( $\geq 80 \%$ Sx based on stand density at the time of the survey), $\mathrm{Pl} / \mathrm{Sx}$ mix ( $21-79 \% \mathrm{Pl}$ and Sx based on SPH at the time of the survey). Two mixed species groups were tested (one PI leading and

[^2]Sx leading), but they did not provide a better fit than a single mixed group.
The same species groups were used in this project as for Riverside, but the age of the stand survey was changed to $10,13,15$, and 18 . In addition, the PMV was 80,90 , and 100 years post-harvest for this project and was 80 years for Riverside.

Two procedures were used to fit the equations for 80,90 , and 100 years post-harvest. First, three separate sets of anamorphic equations were fit for each post-harvest age. Second, one set of anamorphic equations was fit for all three post-harvest times. ${ }^{8}$ The first procedure resulted in equations that better fit the data, but the three equations overlapped at low MSQ values (< 1.5) resulting in inconsistent predictions. For example, for the same MSQ value the PMV 80 years postharvest was slightly higher than the PMV 90 years post-harvest. The second procedure resulted in equations that provided a good fit to the data and produced consistent results. As a result, these equations

Figure 3. Anamorphic curves showing merchantable volume 80 (-), 90 (-) and 100 (-) years after harvest by MSQ 15 years post-harvest. Effective stand ages of 10,13,15, and 18 years are displayed from bottom to top in each set of curves. These curves are for pure Pl at site index 20 m . were chosen as the final set (Figure 3).

### 3.3.4 Site Index

As a first approximation for this project, the procedures to incorporate different site indices and stand ages will follow the methods developed for the Riverside project. For Riverside and this project, the equations to predict future merchantable volume were fit with data from TASS simulations of site index 20 stands. Subsequently adjustment factors were developed for site indices other than 20. An objective of this year's Riverside project is to improve the current model's ability to predict future volumes across a range of site indices. The results of this initiative will be available March 31, 2003.

## Fixed Site Index for Target and Predicted Volumes

The objective of the volume comparison is to focus on the impacts that silviculture performance has on volume growth. For each stratum, the same site index estimates should be used to set the target merchantable volume and determine the PMV. The differences in volume are then associated with differences in stand structure, and not on potential differences in site index. Site index estimates should be based on the best available information for each block (e.g. Site Index Adjustment, growth intercepts, SIBEC). In most cases, with the surveys occurring 15 years post-harvest, the site trees should be tall enough to use growth intercept equations.

[^3]
## Effective Age - Early Height Growth

Early height growth is a function of many variables including site productivity, stock and planting quality, and brush and health impacts; as a result, early height growth can be highly variable. Implicit in TASS and the prediction models are a set of site curves (height-age curves) that define site tree height growth. Once a site index has been chosen for a stratum, there is a defined height-age curve that the site trees follow. Furthermore, for the purposes of this project, the height-age curve is assumed to represent the target height growth pattern. If management practices result in trees growing faster or slower than assumed, then licensees should be rewarded or penalized accordingly. To achieve this, the following steps can be taken:

1) Determine a site index for the leading species in the stratum.
2) Calculate the average site tree height of the leading species from the survey data.
3) Determine the effective total stand age by using the average site tree height and the appropriate height-age curve.

If management practices are better than assumed in the height-age model, then the effective total stand age is older than the physiological age. The reverse is also true (Figure 4).

This method depends on average, realistic site index estimates. If estimated site indices are low, then effective stand ages would be too high on average. These higher ages would not represent better stand management practices, but would be higher because productivity is better than estimated.

## Volume Adjustment by Site Index

The equations for predicted merchantable volume were fit with data for site index 20. Ideally, separate equations would be fit for the

Figure 4. Height-age curve for Pl site index 20 m . Assume the target is set so the stand is 15 years total age 15 years postharvest. For a site index 20 m stand, site trees are assumed to be 5.2 m tall. If the site trees are growing better than expected ( X ), the effective total stand age is 16 years. If they are poorer than expected $(\mathrm{Y})$, the effective total stand is 13 years. full range of site indices; this is currently being tested for Riverside. As an alternative, adjustment factors have been developed to correct for different site indices.

Merchantable volumes at ages 80,90 , and 100 for a range of site indices and initial stand densities were expressed as a percentage of merchantable volume at age 80, 90, and 100 for site index 20 (Figure 5). Similar relationships were found for Pl and Sx , and planted and natural stands. The general pattern observed was percent volume increasing (for site index < 20) or decreasing (for site index > 20) below approximately $2,000 \mathrm{SPH}$ and then remaining fairly constant above this density. Table 3 shows the adjustment factors developed using these results. For stands under $2,000 /$ ha these multipliers will slightly under predict volume for site index > 20 m and slightly over predict for site index $<20 \mathrm{~m}$.

### 3.3.5 Brush and Health Impacts

Brush and health impacts are incorporated into the system by defining if a quadrant is stocked (where stocked quadrants must contain at least one tree which meets the current free-growing standards for health and brush).

### 3.4 Setting TMVs

The TMV should be defined in a higher-level plan (possibly by site series and management zone). Policy decisions are required to set the values used to determine

Figure 5. Proportion of merchantable volume ( $\mathrm{m} 3 / \mathrm{ha)} \mathrm{for} \mathrm{Pl}$ at age 80 by site index and initial stand densities. Data are from TIPSY. TMVs. The current approach
described by Forest Practices Branch sets TMVs at $90 \%$ of the maximum PMV that could be attained with a very aggressive reforestation regime. ${ }^{9}$ The maximum PMV for Riverside is determined using an MSQ of 4.0 , site index 20 m , and an effective age of 12 years. ${ }^{10}$ To determine the TMV, the maximum PMV is then multiplied by 0.9 , and adjusted for lower TSS and different site index (Table 3) if required. It is important that the same equations are used to determine TMVs and PMVs so no bias is introduced.

[^4]
## 4. TRACKING OBLIGATIONS

### 4.1 Overview

This section outlines the steps to summarize the survey data and determine PMVs at 80,90 , or 100 years post-harvest. The six main steps described below are:

1. Choose a post-harvest age for the PMV.
2. Post-stratify the surveyed area.
3. Determine effective age for each stratum.
4. Estimate the MSQ.
5. Estimate the PMV for site index 20.
6. Adjust the PMV for site index.

### 4.2 Choose a Post-Harvest Age for PMV

The model was developed to generate PMVs for 80, 90, or 100 years post-harvest; one of these postharvest times should be chosen for the entire target population. Selecting one post-harvest time results in higher weights (higher volumes) for more productive sites when determining if the overall target volume is achieved. For example, using 80 years for high sites and 100 years for low sites more closely reflects potential future harvest ages; however, it also reduces the difference in the volume targets between high and low sites. The intent of the system is to focus proportionally more effort on the higher sites that provide better returns from silviculture investments.

### 4.3 Post-Stratify the Survey Area

Post-stratify the sampled area after the plot data has been entered into a spreadsheet or database. This is done based on the plots location - not using the plot survey data. The strata are based on: a) species group; b) site index ${ }^{11}$; c) SR or NSR ${ }^{12}$; and TSS (Figure 6, Table 4).

Figure 6. Block map showing plot locations, inventory polygons, and TSS (left) and strata for PMV calculations (right).

[^5]Table 4. Example showing inventory label, TSS and stratum.

| Plot | Inventory label | Species group | Site index <br> (m) | SR/NSR | TSS | Stratum |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | PI8Sx2-13-2.6-15-5-3021/1 | PI | 15 | SR | 1,200 | PI - SI 15 - SR -TSS 1200 |
| 2 | PI8Sx2-13-2.6-15-5-3021/1 | PI | 15 | SR | 1,200 | PI - SI 15 - SR -TSS 1200 |
| 7 | PI8Sx2-13-2.6-15-5-3021/1 | PI | 15 | SR | 1,200 | PI-SI 15 - SR -TSS 1200 |
| 8 | PI8Sx2-13-2.6-15-5-3021/1 | PI | 15 | SR | 1,200 | PI-SI 15 - SR -TSS 1200 |
| 9 | PI8Sx2-13-2.6-15-5-3021/1 | PI | 15 | SR | 1,200 | PI-SI 15 - SR -TSS 1200 |
| 11 | PI8Sx2-13-2.6-15-5-3021/1 | PI | 15 | SR | 800 | PI - SI 15 - SR -TSS 800 |
| 3 | Sx10-13-2.8-15-6-1870/1 | Sx | 15 | SR | 1,200 | Sx-SI 15 - SR - TSS 1200 |
| 4 | Sx10-13-2.8-15-6-1870/1 | Sx | 15 | SR | 800 | Sx - SI 15-SR - TSS 800 |
| 5 | Sx10-13-2.8-15-6-1870/1 | Sx | 15 | SR | 800 | Sx-SI 15 -SR - TSS 800 |
| 6 | Sx10-13-2.8-15-6-1870/1 | Sx | 15 | SR | 800 | Sx-SI 15 -SR - TSS 800 |
| 10 | Sx10-13-2.8-15-6-1870/1 | Sx | 15 | SR | 800 | Sx-SI 15-SR - TSS 800 |

The strata shown in Figure 6 can be determined by overlaying the inventory polygons and the TSS strata. The Fort St. John requirements of stratification by licensee and management zone could also be included in the stratification without further requirements for mapping in the field. Information on stand type (conifer, deciduous, mixed-wood) can also be addressed by assigning inventory polygons to appropriate stand types. Defining divisions within the mixed-wood group will require more work to address changes in species

Figure 7. Relationship of PMV to effective age for different MSQs (PI at site index 20 m ). composition over time. This will be tied to efforts to improve modeling of these stand types.

The need to include effective age in the strata definition was examined. There is a constant linear relationship between effective age and PMV across MSQ values, thus there is no need to stratify based on age (Figure 7).

### 4.4 Determine Effective Age For Each Stratum

Based on inventory information, each stratum will have a defined site index. Using data from all site index plots within the stratum calculate the average height of the site trees of the leading species. The effective stand age can then be derived by looking up the site index and average height in the effective age tables (Appendix II). For each PI-Sx stratum, the effective ages for PI and Sx should be determined separately using the appropriate tables and then averaged to give an effective age for the stratum.

### 4.5 Estimate the MSQ

Calculate the MSQ for the sample plots using all full-measure and count plots in the stratum.

### 4.6 Estimate the PMV for Site Index 20

Choose the appropriate PMV table (Appendix III) based on species composition and 80, 90, or 100 years post-harvest. Use MSQ and effective stand age to determine the PMV.

### 4.7 Adjust the PMV for Site Index

Multiply the PMV by the factor given in Table 3. This gives the final PMV for entry for the silviculture obligation ledger for comparison with the target merchantable volumes.

An example calculation is presented in Appendix IV.

## 5. POTENTIAL LINK TO OTHER SURVEY SYSTEMS \& MONITORING

### 5.1 Link to Other Surveys

The stand survey can be linked with other surveys by using a common sample grid for all surveys. Fullmeasure plots (Section 2) located on the 200 m grid point can be included in all surveys. This will provide the data to develop a chrono-sequence of measurements over time similar to a permanent sample plot. The 200 m grid points are marked with steel pins and GPS (post-processed) UTM coordinates recorded to assist plot relocation for subsequent surveys. The permanent markers at these 200 m sample plots should be installed at the first survey completed in a stand.

As an example, the same plot locations could be measured during pay plot surveys following planting, stocking surveys, and a pole-stage survey done at 30 years of age. The same plot size ( 3.99 m radius) must be used and the same measurements (species, quadrant, estimated heights, damage codes, percent brush cover and brush height ${ }^{13}$ ) must be taken during each survey. This provides data to track changes over time to give feedback on silviculture treatments, and provides data to indirectly check PMV estimates by providing growth data to check TASS projections. We recommend the costs and benefits of this approach be examined.

### 5.2 Link to Growth \& Yield Monitoring

Accurate projections of future merchantable volumes are critical to the success of the proposed survey and modeling system. Establishing a set of monitoring plots to track actual growth and yield of a representative sample of post-harvest regenerated stands provides data to check predicted volumes. The proposed permanent points (one every 4.0 ha on a 200 m grid) provide information on early stand development (approximately ages $0-30$ ) if full-measure plots are repeatedly established over this period. After approximately age 30, larger plots will be needed to obtain accurate estimates of volume and volume growth.

One option to consider is linking the survey system with the proposed growth and yield monitoring program by establishing the growth and yield monitoring plots on the same grid used in the survey system. For example, the growth and yield monitoring plots could be established on a 5.0 km grid using the same UTM base as the 200 m grid used for the full-measure survey plots. If this were done, the growth and yield monitoring plots would not have to be established immediately after harvest to obtain information on early stand growth. Early stand data would be obtained from re-measured full-measure survey plots.

### 5.3 Monitoring Site Productivity

The repeat measurement of the full measure survey plots will also provide valuable information to track the changes in top height (and site index) over time.

[^6]
## 6. FURTHER WORK REQUIRED

### 6.1 BACkGRound

A meeting was held November 5, 2002 in Fort St. John to discuss the applicability of the Riverside system to the Fort St. John TSA. The preceding sections of this report document the work done in the current fiscal year to begin adapting the Riverside system to the Fort St. John TSA. This section documents the top priority issues identified at the November 5 meeting to be addressed in subsequent fiscal years.

### 6.2 Sample Size

The meeting participants agreed that survey plots would be installed on a 100 m grid (i.e., one plot/ha; the same as on Riverside's TFL 49). However, the appropriateness of this sample intensity and the potential to reduce the intensity should be examined after the first year of data collection is complete.

### 6.3 Early Height Growth \& Site Productivity

This survey system relies heavily on measurements of early height growth and site index. These measurements impact the survey system and the link to the volume predictions - which is the core of this system. Furthermore, the information from these surveys will be used to update inventory files and will likely be used for stand-level growth and yield modeling for timber analysis. However, forest managers in the area are generally uncertain of the reliability of current site index estimation tools for the Ft. St. John TSA area. Some of the items discussed where additional work is needed include:

1) Check the growth intercept equations. The meeting participants agreed to use growth intercepts to estimate site index in this survey (where stands are measured 15 years after harvest). However, some trees at these ages may have only a few years growth above breast height, which may introduce additional variation (and possibly bias) into the estimates.
2) Examine early height growth patterns. This survey system relies heavily on the assumption that early height growth patterns in the Ft. St. John area are the same as was used to develop the site index equations, growth intercepts, and the growth models on which this survey is developed. Some practitioners expect that early height growth may be different on some sites in the area (e.g., wet areas).
3) Identify a minimum breast height age and height for estimating site index.
4) Develop ecologically-based site indices for the TSA. There is a need to improve the estimates of potential site index in the TSA. This will positively impact harvest forecast for the area and provide key information for the SFMP. The two main approaches to consider are:
a. SIBEC estimates with PEM or TEM. Some practioners believe that the SIBEC estimates for the area under-estimate site productivity. The MOF recently release the second approximation SIBEC estimates, which may address some of these potential underestimates; however, this should be checked, and more work will be needed to improve these estimates, if required. This approach will also require a completed PEM or TEM for the area.
b. Site index adjustment (SIA) with PEM, TEM, or biophysical model. An SIA project will provide the same results as the SIBEC approach but has the additional advantage of developing site index estimates that more accurately reflect the actual landbase. The

SIA approach can also be done without a completed PEM or TEM, and can be retrofit in the future if a TEM or PEM is completed.
An additional consideration is that a growth and yield monitoring program is being developed for the Fort St. John TSA. There is the option to use the growth and yield monitoring as a subset of the plots for an SIA project for the TSA.
5) Develop an overall plan to address site productivity issues in the short and longer term. The general issue of site productivity in the TSA is that it includes many related components and impacts many aspects of forest management and planning. Consequently, it is worth considering developing a plan to specifically address these and other related issues. This could be done under a general growth and yield plan, or in a plan that specifically addresses site productivity.

### 6.4 Plot Size - Sample Size for Aspen Stands

The recommended plot size for coniferous stands ( 3.99 m radius) is potentially larger than needed for many At stands that may have 200,000 or more stems/ha. Different plot and sample size combinations should be tested at different stand ages to determine optimal procedures.

### 6.5 Development of a Mixed-Wood G\&Y Model

The meeting participants generally agreed that a collaborative effort is desired to promote developing a mixed-wood growth model. One of the first strategic decisions is to decide between taking advantage of work already completed and calibrate an existing model (e.g., TASS) or to commit to the substantial work of developing a new model. It is also important to decide on the appropriate scope for collaborative work to ensure that local issues are adequately addressed. Once these decisions are made, a plan to collect the required data can be developed. Again, the proposed growth and yield monitoring plots could provide a portion of the data required for model calibration. Additional data from designed experiments (such as WESBOGY trials) will also be required.

### 6.6 PMV Models for Other Species

This first approximation of the survey and modeling system addresses only the relatively simple stand types in the area (i.e., PI, Sx, and PISx). More work is needed to adapt the system to different stand types to implement the system across the TSA. The meeting participants agreed that initially the focus would be coniferous stands, and that the models developed for PI and Sx (adapted to different survey and harvest ages) would be appropriate. The following species substitutions could be used in the interim:

1) For Bl use Sx.
2) For Lt use PI.
3) For Sb use Sx.

In the future, the system should be refined to include projections for coniferous stands, mixed-wood stands (coniferous and deciduous leading), and deciduous stands. High priority species combinations were identified as:

1) At
2) $A t S x$
3) AtPI
4) PIAt
5) SxAt
6) $\mathrm{Ep}=\mathrm{At}$

The largest concern is the lack of a mixed-wood model. The meeting participants agreed there is a need to support mixed-wood modeling.

### 6.7 Predicting Future Species Composition

Predicting change in species composition was not addressed in this system. Again, the ability to address this issue depends on having a mixed-wood model that has this capability. This is another reason to promote some form of mixed-wood modeling for the area.

## APPENDIX I - MODEL FITTING DETAILS

A total of 51,960 ( 433 TASS runs $\times 30$ surveys $\times 4$ ages) observations were used to fit the equation PMV $=a+b^{*} M S Q+c^{*} M S Q^{2}$ (Table 5). Parameters $b$ and $c$ were held constant (at 265.774 and -33.251 , respectively) to produce anamorphic curves. A separate intercept (parameter a) was estimated for each species, effective age, and harvest age combination (Table 6).

Table 5. Summary statistics for the fitted model.

| Source | Degrees of <br> Freedom | Sum of Squares <br> $\left(\mathrm{m}^{2}\right)$ | Mean Square <br> $(\mathrm{m})$ | F value |
| :--- | ---: | ---: | ---: | ---: |
| Intercepts | 36 | $269,782,204$ | $7,493,950$ | 21,506 |
| MSQ | 1 | $71,920,496$ | $71,920,496$ | 206,392 |
| MSQ*MSQ | 1 | $38,969,861$ | $38,969,861$ | 111,833 |
| Error | 155842 | $54,305,691$ | 348 |  |
|  |  | $\mathrm{R}^{2}=0.91$ | Root MSE $=18.8$ |  |

## APPENDIX III - TABLES TO ESTIMATE VOLUME 80, 90, \& 100 YEARS POST-HARVEST

The following tables are used to predict future merchantable volumes for site index 20 based on MSQ and effective age values from surveys 15 years post-harvest. In all tables, PMVs for effective ages 10, 13,15 , and 18 were obtained from the fitted equations; all other values were linearly interpolated.

Table 9. Predicted merchantable volumes 80 years post-harvest for pure PI site index 20 stands.

|  | Effective Total Age |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| MSQ | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 |
| 1.0 | 107 | 111 | 116 | 120 | 125 | 129 | 133 | 138 | 142 |
| 1.1 | 126 | 131 | 135 | 140 | 144 | 149 | 153 | 157 | 161 |

## APPENDIX IV - EXAMPLE CALCULATION

## Introduction

This example is based on data collected on four blocks in the Fort St. John TSA in August 2002. It follows the procedures outlined in Section 4 assuming:

1) The four blocks represent the target population.
2) Target stocking standard was 1,200 for all blocks.
3) Blocks were surveyed 15 years after harvest. In reality, not all blocks were surveyed 15 years after harvest so adjustments had to be made to crop tree heights. For example, if a block was actually surveyed 13 years after harvest, two years average crop tree leader growth was added to average crop tree height to approximate crop tree height 15 years after harvest. It was assumed that MSQ would be the same 15 years after harvest as at the time of the survey.
4) Different site index values than those recorded in the surveys. The site index values recorded in the surveys are based on SIBEC data and in comparison to the crop tree heights and ages for most blocks appear low. New site index values were chosen for this example to approximate site indices closer to the true values. ${ }^{16}$

## Choose a Post-harvest Age for PMV

For this example 90 was chosen as the target post-harvest age.

## Post-Stratify the Surveyed Area

Three strata were identified based on species, site index, SR versus NSR, and TSS (Table 18)

Table 18. Description and stratification of Fort St. John blocks surveyed in August 2002.

|  |  |  | Stratum |  |  |  |
| :---: | :--- | :---: | :---: | :---: | :---: | :---: |
| CP/Block | Inventory label $^{\text {a }}$ | Area (ha) | Species | Site index | SR/NSR | TSS |
| $306-2$ | Pli9BI1-11-2.2-15-7-4233/1 | 19.9 | PI | 15 | SR | 1,200 |
| $111-3$ | Sx10-13-2.8-15-6-1870/1 | 16.6 | Sx | 20 | SR | 1,200 |
| $111-4$ | Sx9Pli1-13-2.6-15-5-3021/1 | 16.8 | Sx | 20 | SR | 1,200 |
| $306-2$ | Sx7BI2Pli1-12-2.1-15-6-5200/1 | 29.8 | Sx | 20 | SR | 1,200 |
| $304-6$ | Sx10-14-3.1-18-6-1539/1 | 57.4 | Sx | 22 | SR | 1,200 |

${ }^{a}$ Inventory label, including SIBEC based site index from actual survey data. Site index values listed under Stratum are approximate site indices based on height and age data.

[^9]
## Determine Effective Age, MSQ, and PMV

All of the survey plots were assigned to one of the three strata, and stratum average crop tree heights and mean stocked quadrants were calculated. The average crop tree height and site index were then used to determine the effective age using one of the tables in Appendix II. The effective age and MSQ are then used to determine PMV for site index 20 using one of the tables from Appendix III. Finally, the site index 20 PMV is adjusted to reflect the site index for the stratum (Table 19).

Table 19. Calculated effective ages, MSQs and PMVs for each stratum.

| Species | Stratum <br> Site <br> index |  | SR/NSR | TSS | Avg Site <br> Tree Ht | Effective <br> Age | MSQ | $\mathrm{PMV}_{20}$ <br> $\left(\mathrm{~m}^{3} / \mathrm{ha}\right)$ | Site index <br> Adjustment |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| PI | 15 | SR | 1,200 | 3.0 | 14 | 4.0 | 463 | 0.6 | PMV <br> $\left(\mathrm{m}^{3} / \mathrm{ha}\right)$ |
| Sx | 20 | SR | 1,200 | 3.2 | 17 | 4.0 | 524 | 1.0 | 524 |
| Sx | 22 | SR | 1,200 | 3.1 | 15 | 4.0 | 515 | 1.2 | 618 |

## Compare PMVs and TMVs

For this example TMVs were determined by:

1) Determining the $P M V$ for $M S Q=4.0$, effective age $=17$, and site index $=20$.
2) Multiplying the PMV from step 1 by 0.9 and by the appropriate site index adjustment for the stratum.

In this example, the total predicted merchantable volume exceeds the target by $6,736 \mathrm{~m}^{3}$ or $48 \mathrm{~m}^{3} / \mathrm{ha}$ (Table 20).

Table 20. PMVs and TMVs for each stratum and the population totals.

|  | Stratum <br> Species |  | Site index | SR/NSR | TSS | PMV <br> $\left(\mathrm{m}^{3} / \mathrm{ha}\right)$ | TMV <br> $\left(\mathrm{m}^{3} / \mathrm{ha}\right)$ | Area (ha) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | ---: | | PMV |
| :---: |
| $\left(\mathrm{m}^{3}\right)$ |$⿻$| TMV |
| :---: |
| $\left(\mathrm{m}^{3}\right)$ |

    3 The Riverside models used 10 years post-harvest as the survey time and 80 years post-harvest as the future harvest time.
    ${ }^{4}$ Current indications are that there will be an FII call for research proposals in February 2003.

[^1]:    5 Any type of pin that can be located with a metal detector is acceptable.

[^2]:    ${ }^{7}$ Further details of the model fitting procedures are provided in Appendix I.

[^3]:    8 In the first case different $b$ and $c$ coefficients were fit for each post-harvest time. In the second case, $b$ and $c$ were held constant across the three post-harvest times.

[^4]:    9 Forest Practices Branch. July 9, 2002. Sample design for the 2002 pilot of Riverside's new approach to silviculture obligations. Unpublished. Available from Pat Martin.
    10 Riverside surveys are conducted 10 years post-harvest. An effective age of 12 assumes late winter harvest early in the calendar year, and 1-year-old stock planted in the spring so that the trees are 2 years old in the fall of the year harvesting occurred. Surveys are assumed to occur 10 years post-harvest in the fall.

[^5]:    11 Initial adjustments for site index (Table 3) result in a linear relationship between site index and PMV across MSQ values, suggesting there is no need to stratify by site index. However, site index is included as it is expected improved adjustments for site index will not be linear.
    12 The definitions of SR and NSR are a policy decision.

[^6]:    13 If brush is a significant management issue, then surveys should be done at the same time of the year to ensure consistent \% cover estimates.

[^7]:    14 These are the site curves currently used in TASS. They are not in the current versions of Site Tools or Tipsy. The Thrower (1994) and Nigh and Love (1999) PI curves are spliced together by using the Nigh/Love curve below breast height age 0 , the Thrower curve above breast height 2 , and linearly interpolating heights between breast height age 0 and 2. Nigh, G.D. 1999. Smoothing top height estimates from two lodgepole pine height models. B.C. Min. For., Res. Br., Victoria, B.C. Ext. Note 30. J.S. Thrower and Associates Ltd. 1994. Revised height-age curves for lodgepole pine and interior spruce in British Columbia. Report to the Res. Br., B.C. Min. For., Victoria, B.C. 27 p.

[^8]:    15 These are the site curves currently used in TASS. They are not in the current versions of Site Tools or Tipsy. These curves result from the splicing together of the juvenile height curves by Nigh and Love (2000) and the heightage curves by Goudie (1984). Nigh, G.D. and B.A. Love. 2000. Juvenile height development in interior spruce stands of British Columbia. West. J. Appl. For. 15: 117-121. Goudie, J.W. 1984. Height growth and site index curves for lodgepole pine and white spruce and interim managed stand yield tables for lodgepole pine in British Columbia. B.C. Min. For., Res. Br. Unpubl. Rep. 75 p.

[^9]:    16 In future surveys it is recommended that growth intercept equations be used to determine site indices rather than SIBEC estimates.
